⁸ Abstract

Eye-tracking has become a valuable tool for studying cognitive processes in second language (L2) acquisition and bilingualism (Godfroid et al., 2024). While research-grade infrared eye-trackers are commonly used, there are a number of issues that limit its wide-spread adoption. Recently, consumer-based webcam eye-tracking has emerged as an attractive alternative, requiring only internet access and a personal webcam. However, webcam eye-tracking presents unique design and preprocessing challenges that must be addressed for valid results. To help researchers overcome these challenges, we developed a comprehensive tutorial focused on visual world webcam eye-tracking for L2 language research. Our guide will cover all key steps, from design to data preprocessing and analysis, where we highlight the R package `webgazeR`, which is open source and freely available for download and installation: <https://github.com/jgeller112/webgazeR>. We offer best practices for environmental conditions, participant instructions, and tips for designing visual world experiments with webcam eye-tracking. To demonstrate these steps, we analyze data collected through the Gorilla platform (Anwyl-Irvine et al., 2020) using a single word Spanish visual world paradigm (VWP) and show competition within and between L2/L1. This tutorial aims to empower researchers by providing a step-by-step guide to successfully conduct visual world webcam-based eye-tracking studies. To follow along with this tutorial, please download the entire manuscript and its accompanying code with data from here: https://github.com/jgeller112/L2_VWP_Webcam.

Keywords: VWP, Tutorial, Webcam eye-tracking, R, Gorilla, Spoken word recognition, L2 processing

¹ Eye-tracking technology, which has a history spanning over a century, has seen remarkable advancements. In the early days, eye-tracking sometimes required the use of contact lenses fitted with search coils, often requiring anesthesia, or the attachment of suction cups to the sclera of the eyes (Płużyczka, 2018).

4 These methods were not only cumbersome for the researcher, but also uncomfortable and invasive for par-
5 ticipants. Over time, such approaches have been replaced by non-invasive, lightweight, and user-friendly
6 systems. Today, modern eye-tracking technology is widely accessible in laboratories worldwide, enabling
7 researchers to tackle critical questions about cognitive processes . This evolution has had a profound impact
8 on fields such as psycholinguistics and bilingualism, opening up new possibilities for understanding how
9 language is processed in real time (Godfroid et al., 2024).

10 Despite its widespread adoption in cognitive and behavioral research, eye-tracking technology faces
11 several obstacles that can limit its accessibility and integration into research programs. One significant chal-
12 lenge is the specialized expertise required to operate research-grade eye-trackers. Proper calibration, data
13 collection, and analysis often demand extensive training, meaning that studies typically need to be con-
14 ducted in controlled lab environments by trained students or faculty. This reliance on specialized skills can
15 be a barrier for researchers who lack access to experienced personnel or institutional support.

16 Cost is another major limitation. High-quality eye-tracking equipment can be prohibitively expen-
17 sive, with prices ranging from a few thousand dollars (e.g., Gazepoint; www.gazept.com) to tens of thousands
18 of dollars for more advanced systems (e.g., Tobii; www.tobii.com, SR Research; www.sr-research.com).
19 These costs extend beyond the hardware, as proprietary software, maintenance, and upgrades can further
20 strain research budgets. Consequently, institutions with limited funding may find it challenging to invest in
21 or sustain eye-tracking research.

22 Time constraints also pose a significant hurdle. Many labs possess only a limited number of eye-
23 trackers, restricting the number of participants that can be run simultaneously. This limitation can lead to
24 prolonged data collection periods, especially for studies requiring large sample sizes or longitudinal designs.
25 The time-intensive nature of both data collection and the subsequent analysis can deter researchers from
26 integrating eye-tracking into their projects.

27 In addition to the above, an issue often not discussed is the burden placed on participants. Partici-
28 pating in eye-tracking studies requires participants to come into the lab. This significantly limits the sample
29 or population researchers can recruit. Behavioral science research, in general, frequently suffers from a lack
30 of diversity, relying heavily on participants who are predominantly Western, Educated, Industrialized, Rich,
31 Democratic, and able-bodied (WEIRD-A) (Henrich et al., 2010). This focus often excludes individuals from

32 geographically dispersed areas, those from lower socioeconomic backgrounds, and people with disabilities
33 who may face barriers to accessing research facilities. In language research, this issue is particularly evident,
34 as it often prioritizes modal listeners and speakers, which are typically characterized as young, monolingual,
35 and neurotypical (Blasi et al., 2022; Bylund et al., 2024; McMurray et al., 2010)

36 Collectively, these challenges—expertise, cost, time, and space/location—mean that not all re-
37 searchers have the resources or capacity to incorporate eye-tracking into their research program nor recruit
38 the sample they want, thereby limiting the broader adoption of this powerful methodology in fields where it
39 could provide valuable insights.

40 Eye-tracking outside the lab

41 Methods that allow participants to use their own equipment from anywhere in the world offer a
42 potential solution to the issues outlined above, enabling researchers to recruit more diverse and disadvantaged
43 samples and explore a broader range of questions (Gosling et al., 2010). The shift toward online behavioral
44 experiments has been gradually increasing in the behavioral sciences and has become ever more important
45 since the COVID-19 pandemic forced many to explore options outside the lab (Anderson et al., 2019; Rodd,
46 2024). The *onlineification* of behavioral research has prompted the development of eye-tracking methods
47 that do not rely on traditional lab settings.

48 One method, manual eye-tracking (Trueswell, 2008), involves using video recordings of participants,
49 which can be collected through online teleconferencing platforms such as Zoom (www.zoom.com). Here eye
50 gaze (direction) is manually analyzed post-hoc frame by frame from these recordings. However, this method
51 raises ethical and privacy concerns, as not all participants may be comfortable having their videos recorded
52 and stored for analysis.

53 Another method, which is the focus of this tutorial, is automated eye-tracking or webcam eye-
54 tracking. Webcam eye-tracking requires three things: 1. A personal computer. 2. An internet connection
55 and 3. A purchased or pre-installed webcam. Gaze information can be collected via a web browser. One
56 common method to perform webcam eye-tracking is through an open source, free, and actively maintained
57 JavaScript library plugin called WebGazer.js (Papoutsaki et al., 2016). This plugin is already incorporated
58 into several popular experimental platforms (e.g., Gorilla, *jsPsych*, PsychoPy, and PCIbex; (Anwyl-Irvine
59 et al., 2020; Leeuw, 2015; Peirce et al., 2019; Zehr & Schwarz, 2018). WebGazer.js runs locally through
60 a person's personal computer via a browser. A benefit of WebGazer.js is that it does not require users to
61 download any software, and is fully integrated in the browser, making it extremely easy to start webcam
62 eye-tracking. In addition, videos taken from webcams are not recorded and saved which eliminates some of
63 the ethical and privacy concerns.

64 WebGazer.js utilizes facial feature detection to estimate gaze positions in real time through a webcam.
65 At each time point, determined by the sampling rate, x and y coordinates of the gaze are recorded. The
66 system employs machine learning to analyze the relative movement of the eyes and infer the gaze location
67 on the screen. To enhance accuracy, calibration and validation procedures are implemented, during which
68 participants fixate on markers with known positions on the screen.

69 During calibration, users interact with visual stimuli by looking at and clicking on randomly placed
70 dots or by following a moving dot across the screen. This interaction allows the system to map eye positions
71 to specific screen coordinates. In the subsequent validation phase, participants repeat a similar procedure,
72 enabling researchers to assess the accuracy of the gaze predictions. These procedures provide an estimate of
73 the deviation between the calibrated eye-tracking data (where the system predicts the participant looked) and
74 the actual known positions of the stimuli, thus allowing for the evaluation and refinement of gaze estimation
75 accuracy.

76 It is important to note that WebGazer.js is not the only method available. Other methods have been
77 implemented by companies like Tobii (www.tobii.com) and Labvanced (Kaduk et al., 2024). However,
78 because these methods are proprietary, they are less accessible and difficult to reproduce.

79 The algorithms underlying webcam-based eye tracking differ significantly from those used in
80 research-grade eye trackers. Research-grade systems commonly employ video-based recording and rely on
81 one or more cameras and the pupil-corneal reflection (P-CR) method to track gaze with high precision (Carter
82 & Luke, 2020). This method utilizes infrared light to illuminate the eyes, capturing reflections (known as
83 glints) from the cornea and pupil. High-speed cameras simultaneously capture images at rates of hundreds or
84 thousands of frames per second to measure eye position. By combining data from the corneal reflections and
85 pupil location, these systems calculate gaze direction and position. To derive real-world information about
86 where participants looked, a transformation is required, which is usually done mathematically (Hooge et al.,
87 2024).

88 This leads to an important question: how does consumer-grade webcam eye tracking compare to
89 research-grade systems? While validation studies are ongoing, webcam-based eye trackers generally exhibit
90 reduced spatiotemporal accuracy. Studies have reported that these systems achieve spatial accuracy and
91 precision exceeding 1° of visual angle, with latencies ranging from 200 ms to 1000 ms (Kaduk et al., 2024;
92 Semmelmann & Weigelt, 2018; Slim et al., 2024; Slim & Hartsuiker, 2023). Furthermore, the sampling rate
93 of webcam-based systems is much lower, typically capped at 60 Hz, with most studies reporting average or
94 median rates around 30 Hz (Bramlett & Wiener, 2024; Prystauka et al., 2024). Unlike research-grade systems,
95 webcam eye trackers do not use infrared light; instead, they rely on ambient light from the participant's
96 environment. This dependency introduces additional variability in tracking performance.

97 To compare, a study of 15 research-grade eye-trackers by Hooge et al. (2024) found that precision
98 ranged from 0.1° to 0.35° , while accuracy ranged from 0.3° to 0.75° . Additionally, research-grade eye-
99 trackers have low latency and can achieve high sampling rates—for example, the SR EyeLink 1000 Plus can
100 sample at 2,000 Hz. These advanced capabilities make research-grade systems ideal for studies requiring
101 high temporal and spatial resolution.

102 **Bringing the visual world paradigm (VWP) online**

103 Despite the differences between research-grade and consumer grade eye-tracking, a number of stud-
104 ies have begun to look at if lab-based results replicate online using webcam eye-tracking. Most relevant to
105 this tutorial are online replications using the VWP (Tanenhaus et al., 1995; cf. Cooper, 1974). For the past

106 25 years, the VWP has been a dominant force in language research, helping researchers tackle a wide range of
107 topics, including sentence processing (Altmann & Kamide, 1999; Huettig et al., 2011; Kamide et al., 2003),
108 word recognition (Allopenna et al., 1998; Dahan et al., 2001; Huettig & McQueen, 2007; McMurray et al.,
109 2002), bilingualism (Hopp, 2013; Ito et al., 2018; Rossi et al., 2019), and the effects of brain damage on
110 language (Mirman & Graziano, 2012; Yee et al., 2008).

111 What makes the widespread use of the VWP even more remarkable is the simplicity of the task. In a
112 typical VWP experiment, participants view a display containing several objects (in the form of pictures) and
113 are asked to select one of them by pointing or clicking. As they listen to a spoken word or phrase that identifies
114 the target object, their eye movements are recorded in real time. The standard finding using the VWP is that
115 listeners show eye movements to the picture that represents the spoken word, while demonstrating predictive
116 processing, such that eye movements to pictures occur before an entire word is available. Remarkably, looks
117 to each object align very closely—and with precise timing—with the mental activation of the word or concept
118 it represents. This provides a unique and detailed view of how cognitive processes unfold in real time

119 Most research on visual world eye-tracking has been conducted in laboratory settings using research-
120 grade eye-trackers. However, several attempts have been made to conduct these experiments online using
121 webcam-based eye-tracking. Most online VWP replications have focused on sentence-based language pro-
122 cessing. These studies have looked at effects of set size and determiners (Degen et al., 2021), verb semantic
123 constraint (Prystauka et al., 2024; Slim & Hartsuiker, 2023), grammatical aspect and event comprehension
124 (Vos et al., 2022), and lexical interference (Prystauka et al., 2024).

125 More relevant to the current paper are findings from single-word VWP studies conducted online.
126 To date, only one study has investigated visual world webcam eye-tracking with single words. Slim et al.
127 (2024) examined a phonemic cohort task. In the cohort task, pictures were displayed randomly in one of four
128 quadrants, and participants were instructed to fixate on the target based on the auditory cue. On each trial,
129 one of the pictures was phonemically similar to the target in onset (e.g., *MILK – MITTEN*).

130 They were able to observe significant fixations to the cohort compared to the control condition,
131 replicating lab-based single word VWP experiments with research grade eye-trackers (e.g., Allopenna et al.,
132 1998). However, Slim et al. (2024) only observed these competition effects in a later time window compared
133 to traditional, lab-based eye-tracking.

134 It is important to note, however, that while these studies represent successful replication attempts,
135 there is an important caveat. Most notably, some studies (e.g., Degen et al., 2021; Slim et al., 2024; Slim
136 & Hartsuiker, 2023) reported considerable delays in the temporal onset of effects. Several factors likely
137 contribute to these delays, including reduced spatial precision, computational demands, the size of areas of
138 interest (AOIs), and the number of calibrations performed (Degen et al., 2021).

139 More recent work has addressed these limitations by utilizing an updated version of WebGazer.js and
140 using different experimental platforms. For instance, Vos et al. (2022) demonstrated a significant reduction in
141 delays—approximately 50 ms—when comparing lab-based and online versions of the VWP using an updated
142 version of WebGazer.js within the jsPsych framework (Leeuw, 2015). Furthermore, studies by Prystauka et
143 al. (2024) and Bramlett and Wiener (2024), which leveraged the Gorilla platform alongside the improved

¹⁴⁴ WebGazer algorithm, reported effects comparable to those observed in traditional lab-based VWP studies.

¹⁴⁵ These findings underscore the potential of the online version of the VWP, powered by webcam eye-
¹⁴⁶ tracking, to achieve results similar to those of traditional lab-based methods. Importantly, they demonstrate
¹⁴⁷ that this approach can effectively be used to study competition effects in single-word speech perception.

¹⁴⁸ **Tutorial**

¹⁴⁹ Taken together, it seems that webcam eye-tracking is a viable alternative to lab-based eye-tracking.
¹⁵⁰ Given this, we aimed to support researchers in their efforts to conduct high-quality webcam eye-tracking
¹⁵¹ studies with the VWP. While a valuable tutorial on webcam eye-tracking in the VWP already exists (Bramlett
¹⁵² & Wiener, 2024), we believe there is value in having multiple resources available to researchers. To this end,
¹⁵³ we sought to expand on the tutorial by Bramlett and Wiener (2024) by incorporating many of their useful
¹⁵⁴ recommendations, but also offering an R package to help streamline data pre-processing.

¹⁵⁵ The purpose of this tutorial is to provide an overview of the basic set-up and design features of an
¹⁵⁶ online VWP task using the Gorilla platform (Anwyl-Irvine et al., 2020) and to highlight the pre-processing
¹⁵⁷ steps needed to analyze webcam eye-tracking data. Here we use the popular open source programming
¹⁵⁸ language R and introduce the `webgazeR` package (Geller & Prystauka, 2024) to facilitate pre-processing of
¹⁵⁹ webcam data. To highlight the steps needed to process webcam eye-tracking data we present data from a
¹⁶⁰ Spanish spoken word VWP with L2 Spanish speakers. To our knowledge, L2 processing and competitor
¹⁶¹ effects have not been looked at in the online version of the VWP.

¹⁶² The structure of the tutorial will be as follows. We first outline the general methods used to conduct
¹⁶³ a visual world webcam eye-tracking experiment. Next, we detail the data preprocessing steps required to
¹⁶⁴ prepare the data for analysis. Finally, we demonstrate one statistical approach for analyzing our preprocessed
¹⁶⁵ data, highlighting its application and implications.

¹⁶⁶ To promote transparency and reproducibility, this tutorial was written in R (R Core Team, 2024)
¹⁶⁷ using Quarto (Allaire et al., 2024), an open-source publishing system that allows for dynamic and static
¹⁶⁸ documents. This allows figures, tables, and text to be programmatically included directly in the manuscript,
¹⁶⁹ ensuring that all results are seamlessly integrated into the document. To increase computational reproducibil-
¹⁷⁰ ity we use the `rix` (Rodrigues & Baumann, 2025) package which harnesses the power of the `nix` (Dolstra &
¹⁷¹ contributors, 2023) ecosystem to help with computational reproducibility. Not only does this give us a snap-
¹⁷² shot of the packages used to create the current manuscript, but it also takes a snapshot of system dependencies
¹⁷³ used at run-time. This way reproducers can easily re-use the exact same environment by installing the `nix`
¹⁷⁴ package manager and using the included `default.nix` file to set up the right environment. The `README` file
¹⁷⁵ in the GitHub repository contains detailed information on how to set this up to reproduce the contents of the
¹⁷⁶ current manuscript. We have also included a video tutorial.

177

L2 VWP Webcam Eye-tracking

178 To highlight the preprocessing steps required to analyze webcam eye-tracking data, we examined the
179 competitive dynamics of second-language (L2) learners of Spanish, whose first language is English, during
180 spoken word recognition. Specifically, we investigated both within-language and cross-language (L2/L1)
181 competition using webcam-based eye-tracking.

182 It is well established that competition plays a critical role in language processing (Magnuson et al.,
183 2007). In speech perception, as the auditory signal unfolds over time, competitors (or cohorts)—phonological
184 neighbors that differ from the target by an initial phoneme—become activated. To successfully recognize the
185 spoken word, these competitors must be inhibited or suppressed. For example, as the word *wizard* is spoken,
186 cohorts like *whistle* might also be briefly activated and in order for *wizard* to be recognized, *whistle* must be
187 suppressed. A key question in the L2 literature is whether competition can occur cross-linguistically, with
188 interactions between a speaker’s first language (L1) and second language (L2). Recent work by Sarrett et
189 al. (2022) explored this question using carefully designed stimuli to examine within- and between linguis-
190 tic (L2/L1) competition in adult L2 Spanish learners using a Spanish VWP. Their study included two key
191 conditions:

- 192 1. Spanish-Spanish (within) condition: A Spanish competitor was presented alongside the target word.
193 For example, if the target word spoken was *cielo* (sky), the Spanish competitor was *ciencia* (science).
- 194 2. Spanish-English (cross-linguistic) condition: An English competitor was presented for the Spanish target
195 word. For example, if the target word spoken was *botas* (boots), the English competitor was *border*.

196 Sarrett et al. (2022) also included a no competition condition where the Spanish-English pairs were
197 not cross-linguistic competitors (e.g., *frontera* as the target word and *botas* - *boots* as an unrelated item in
198 the pair). They observed competition effects in both of the critical conditions: within (e.g., *cielo* - *ciencia*)
199 and between (e.g., *botas* - *border*). For this tutorial, we collected data to conceptually replicate their pattern
200 of findings.

201 There are two key differences between our dataset and the original study by Sarrett et al. (2022) worth
202 noting. First, Sarrett et al. (2022) focused on adult L2 Spanish speakers and posed more fine-grained ques-
203 tions about the time course of competition and resolution and its relationship with L2 language acquisition.
204 Second, unlike Sarrett et al. (2022), who measured Spanish proficiency objectively using LexTALE-esp
205 (Izura et al., 2014)), we relied on Prolific’s filters to recruit L2 Spanish speakers.

206 Our primary goal here was to demonstrate the pre-processing steps required to analyze webcam-
207 based eye-tracking data. A secondary goal was to provide evidence of L2 competition within and between
208 or cross-linguistically using this methodology. To our knowledge, no papers have looked at spoken word
209 recognition and competition using online methods. It is our hope that researchers can use this to test more
210 detailed questions about L2 processing using webcam-based eye-tracking.

211 **Method**

212 All tasks herein can be previewed here (<https://app.gorilla.sc/openmaterials/953693>). The
213 manuscript, data, and R code can be found on Github (https://github.com/jgeller112/webcam_gazeR_VWP).

214 **Participants**

215 We recruited participants from Prolific, a participant recruitment platform, who were: (1) between
216 the ages of 18 and 36 years old, (2) native English speakers, (3) were also fluent in Spanish, and (4) residents of
217 the US. All participants were taken to the Gorilla hosting and experiment platform (www.gorilla.sc; (Anwyl-
218 Irvine et al., 2020). The participant flow is shown in Figure 1. A total of 187 participants consented to
219 participate in the study. Of these, 121 passed the headphone screener checkpoint and 111 proceeded to
220 the VWP. Out of the 111 participants that entered the VWP, 91 total made it to the final surveys at the
221 end. Among those, 32 participants successfully completed the VWP task with at least 100 trials, while 79
222 participants did not provide adequate data to be included (failed calibration attempts). Table 1 provides
223 basic demographic information about the participants who completed the full experiment. After applying
224 additional exclusion criteria (accuracy < 80%) and excessive missing eye-data (> 30%), the final sample
225 consisted of 28 participants with usable eye-tracking data.

226 **Materials**

227 **VWP..**

228 **Items.** We adapted materials from Sarrett et al. (2022). In their cross-linguistic VWP, participants
229 were presented with four pictures and a spoken Spanish word and had to select the image that matched the
230 spoken word by clicking on it. The word stimuli for the experiment were chosen from textbooks used by
231 students in their first and second year college Spanish courses.

232 The item sets consisted of two types of phonologically-related word pairs: one pair of Spanish-
233 Spanish words and another of Spanish-English words. The Spanish-Spanish pairs were unrelated to the
234 Spanish-English pairs. All the word pairs were carefully controlled on a number of dimensions (see Sarrett
235 et al., 2022).

236 There were three experimental conditions: (1) the Spanish-Spanish (within) condition, where one of
237 the Spanish words was the target and the other was the competitor; (2) the Spanish-English (cross-linguistic)
238 condition, where a Spanish word was the target and its English phonological cohort served as the competitor;
239 and (3) the No Competitor condition, where the Spanish word did not overlap with any other word in the set.
240 The Spanish-Spanish condition had twice as many trials as the other conditions due to the interchangeable
241 nature of the target and competitor words in that pair.

242 There were 15 sets of 4 items (half the number of sets used in (Sarrett et al., 2022). Each item within a
243 set was repeated 4 times as the target word. This yielded 240 trials (15 sets × 4 items per set × 4 repetitions).
244 Each item set consisted of one Spanish-Spanish cohort pair and one Spanish-English cohort pair. Both

Participant flow, from recruitment to final sample

245 items in a Spanish-Spanish pair had a “reciprocal” competitor relationship (that is, we could test activation
 246 for *cielo* given *ciencia*, and for *ciencia* given *cielo*). Consequently, there were 120 trials in the Spanish-
 247 Spanish condition. In contrast, only one item from the Spanish-English pair had the specified competitor
 248 relationship (we could test activation for *frontera border*, given *botas*, but when hearing *frontera*, there was
 249 no competitor). Thus, there were only 60 trials for each the Spanish-English competition as well as the No
 250 Competitor condition. Items occurred in each of the four corners of the screen on an equal numbers of trials.

251 **Stimuli.** In Sarrett et al. (2022) all auditory stimuli were recorded by a female bilingual speaker
 252 whose native language was Mexican Spanish and also spoke English. Stimuli were recorded in a sound-
 253 attenuated room sampled at 44.1 kHz. Auditory tokens were edited to reduce noise and remove clicks. The
 254 auditory tokens were then amplitude normalized to 70 dB SPL. For each target word, there were four separate
 255 recordings so each instance was unique.

256 Visual stimuli were images from a commercial clipart database that were selected by a consensus

257 method involving a small group of students. All .wav files were converted to .mp3 for online data collection.
258 All stimuli can be found here: <https://osf.io/mgkd2/>.

259 **Headphone screener.** Headphones were required for all participants. To ensure this, we used a six-
260 trial task taken from Woods et al. (2017). On each trial, three tones of the same frequency and duration were
261 presented sequentially. One tone had a lower amplitude than the other two tones. Tones were presented in
262 stereo, but the tones in the left and right channels were 180 out of phase across stereo channels—in free field,
263 these sounds should cancel out or create distortion, whereas they will be perfectly clear over headphones.
264 The listener picked which of the three tones was the quietest. Performance is generally at the ceiling when
265 wearing headphones but poor when listening in the free field (due to phase cancellation).

266 **Participant background and experiment conditions questionnaire.** Participants completed a de-
267 mographic questionnaire as part of the study. The questions covered basic demographic information, includ-
268 ing age, gender, spoken dialect, ethnicity, and race.

269 Participants also answered a series of questions related to their personal health and environmental
270 conditions during the experiment. These questions addressed any history of vision problems (e.g., corrected
271 vision, eye disease, or drooping eyelids) and whether they were currently taking medications that might impair
272 judgment. Participants also indicated if they were wearing eyeglasses, contacts, makeup, false eyelashes, or
273 hats.

274 The questionnaire inquired about their environment, asking if there was natural light in the room, if
275 they were using a built-in camera or an external one (with an option to specify the brand), and their estimated
276 distance from the camera. Participants were asked to estimate how many times they looked at their phone or
277 got up during the experiment and whether their environment was distraction-free.

278 Additional questions assessed the clarity of calibration instructions, allowing participants to suggest
279 improvements, and asked if they were wearing a mask during the session. These questions aimed to gather
280 insights into personal and environmental factors that could impact data quality and participant comfort during
281 the experiment.

282 To gauge L2 experience, we asked participants when they started speaking Spanish, how many years
283 of Spanish speaking experience they had, and to provide, on a scale between 0-100, how often they use
284 Spanish in their daily lives.

285 **Procedure**

286 All tasks were completed in a single session, lasting approximately 45 minutes. The tasks were
287 presented in a fixed order: consent, headphone screener, spoken word VWP, and questionnaire items.

288 The experiment was programmed in the Gorilla Experiment Platform (Anwyl-Irvine et al., 2020),
289 with personal computers as the only permitted device type. Upon entering the online study, participants
290 received general information to decide if they wished to participate, after which they provided informed
291 consent. Participants were then instructed to adjust the volume to a comfortable level while noise played.

292 Next, participants completed a headphone screening test. They had three attempts to pass this test.

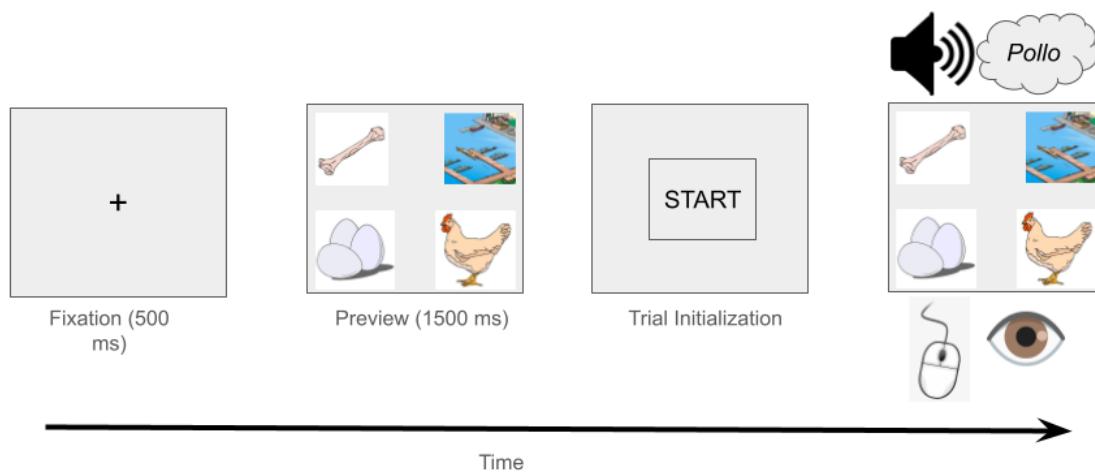

293 If unsuccessful by the third attempt, participants were directed to an early exit screen, followed by the ques-
294 tionnaire.

295 For those who passed the screening, the next task was the VWP. This began with instructional videos
296 providing specific guidance on the ideal experiment setup for eye-tracking and calibration procedures. You
297 can view the videos here: <https://osf.io/mgkd2/>. Participants were then required to enter full-screen mode
298 before calibration. A 9-point calibration procedure was used. Calibration occurred every 60 trials for a
299 total of 3 calibrations. Participants had three attempts to successfully complete each calibration phase. If
300 calibration was unsuccessful, participants were directed to an early exit screen, followed by the questionnaire.

301 In the main VWP task, each trial began with a 500 ms fixation cross at the center of the screen. This
302 was followed by a preview screen displaying four images, each positioned in a corner of the screen. After
303 1500 ms, a start button appeared in the center. Participants clicked the button to confirm they were focused
304 on the center before the audio played. Once clicked, the audio was played, and the images remained visible.
305 Participants were instructed to click the image that best matched the spoken target word, while their eye
306 movements were recorded. Eye movements were only recorded on that screen. Figure 2 displays the VWP
307 trial sequence.

Figure 2

VWP trial schematic

308 After completing the main VWP task, participants proceeded to the final questionnaire, which in-
309 cluded questions about the eye-tracking task and basic demographic information. Participants were then
310 thanked for their participation.

311 **Preprocessing data**

312 After the data is collected you can begin preprocessing your data. Below we highlight the steps
313 needed to preprocess your webcam eye-tracking data and get it ready for analysis. For some of this prepro-
314 cessing we will use the newly created `webgazeR` pacckage (v. 0.1.0) which is an extension of the `gazeR`
315 package (Geller et al., 2020) which was created to analyze VWP data from lab-based studies.

316 For preprocessing visual world webcam eye data, we follow six general steps:

- 317 1. Reading in data
318 2. Data exclusion
319 3. Combining trial- and eye-level data
320 4. Assigning areas of interest (AOIs)
321 5. Time binning
322 6. Aggregating (optional)

323 For each of these steps, we will display R code chunks demonstrating how to perform each step with
324 helper functions (if applicable) from the `webgazeR` (Geller & Prystauka, 2024) package in R.

325 **Load packages**

326 **Package Installation and Setup.** Before turning to the preprocessing code below, we will need to
327 make sure all the necessary packages are installed. The code will not run if the packages are not installed
328 properly. If you have already installed the packages mentioned below, then you can skip ahead and ignore this
329 section. To install the necessary packages, simply run the following code - it may take some time (between
330 1 and 5 minutes to install all of the libraries so you do not need to worry if it takes some time).

331 **webgazeR installation.** The `webgazeR` package is installed from the Github repository using the
332 `remotes` (Csárdi et al., 2024) package.

```
library(remotes) # install github repo  
  
remotes::install_github("jgeller112/webgazeR")
```

333 Once this is installed, `webgazeR` can be loaded along with additional useful packages. The following
334 code will load the required packages or install them if you do not have them on your system.

```
# List of required packages
required_packages <- c(
  "tidyverse",      # data wrangling
  "here",           # relative paths instead of absolute aids in reproducibility
  "tinytable",       # nice tables
  "janitor",        # functions for cleaning up your column names
  "webgazeR",        # has webcam functions
  "readxl",          # read in Excel files
  "ggokabeito",      # color-blind friendly palettes
  "flextable",        # Word tables
  "permuco",         # permutation analysis
  "foreach",          # permutation analysis
  "geomtextpath",      # for plotting labels on lines of ggplot figures
  "cowplot"          # combine ggplot figures
)
```

335 Once `webgazeR` and other helper packages have been installed and loaded the user is ready to start
 336 cleaning your data.

337 ***Reading in data***

338 **Behavioral, trial-level, data.** To process eye-tracking data you will need to make sure you have both
 339 the behavioral data and the eye-tracking data files. We have all the data needed in the repository by navigating
 340 to the L2 subfolder from the main project directory (`~/data/L2`). For the behavioral data, Gorilla produces a
 341 `.csv` file that includes trial-level information (here contained in the object `L2_data`). The files needed are
 342 called `data_exp_196386-v5_task-scf6.csv` and `data_exp_196386-v6_task-scf6.csv`. We have
 343 two files because we ran a modified version of the experiment.

344 The `.csv` files contain meta-data for each trial, such as what picture were presented on each
 345 trial, which object was the target, reaction times, audio presentation times, what object was clicked on, etc.
 346 To load our data files into our R environment, we use the `here` (Müller, 2020) package to set a relative
 347 rather than an absolute path to our files. We read in the data files from the repository for both versions of
 348 the task and merge the files together. `L2_data` merges both `data_exp_196386-v5_task-scf6.csv` and
 349 `data_exp_196386-v6_task-scf6.csv` into one object.

```
# load in trial level data
# combine data from version 5 and 6 of the task
L2_1 <- read_csv(here("data", "L2", "data_exp_196386-v5_task-scf6.csv"))
L2_2 <- read_csv(here("data", "L2", "data_exp_196386-v6_task-scf6.csv"))
```

```
L2_data <- rbind(L2_1, L2_2) # bind the two objects together
```

350 **Eye-tracking data.** Gorilla currently saves each participant's eye-tracking data on a per-trial ba-
 351 sis. The raw subfolder in the project repository contains the eye-tracking files by participant for each trial
 352 individually (~/data/L2/raw). Contained in those files, we have information pertaining to each trial such as
 353 participant id, time since trial started, x and y coordinates of looks, convergence (the model's confidence
 354 in finding a face (and accurately predicting eye movements), face confidence (represents the support vector
 355 machine (SVM) classifier score for the face model fit), and information pertaining to the the AOI screen
 356 coordinates (standardized and user-specific). The vwp_files_L2 object below contains a list of all the files
 357 contained in the folder. Because vwp_files_L2 contains trial data as well as calibration data, we remove
 358 the calibration trials and save the non-calibration to to vwp_paths_filtered_L2.

```
# Get the list of all files in the folder
vwp_files_L2 <- list.files(here::here("data", "L2", "raw"), pattern =
  "\\.xlsx$", full.names = TRUE)
# Exclude files that contain "calibration" in their filename
vwp_paths_filtered_L2 <- vwp_files_L2[!grepl("calibration", vwp_files_L2)]
```

359 When data is generated from Gorilla, each trial in your experiment is saved as an individual
 360 file. Because of this, we need some way to take all the individual files and merge them together. The
 361 merge_webcam_files() function from webgazeR merges trial-level data from each participant into a sin-
 362 gle tibble or data frame. Before running the merge_webcam_files() function, ensure that your working
 363 directory is set to where the files are stored. The merge_webcam_files() function reads in all the .xlsx
 364 files from the raw subfolder, binds them together into one dataframe, and cleans up the column names. The
 365 function then filters the data to include only rows where the type is “prediction” and the screen_index
 366 matches the specified value (in our case, screen 4 is where we collected eye-tracking data). If you recorded
 367 across multiple screens the screen_index argument can take multiple values (e.g., screen_index= c(1,
 368 4, 5) will take eye-tacking information from screens, 1, 4, and 5)). merge_webcam_files() also renames
 369 the spreadsheet_row column to trial and sets both trial and subject as factors for further analysis in
 370 our pipeline. As a general note, all steps should be followed in order due to the renaming of column names.
 371 If you encounter an error it might be because column names have not been changed.

```
setwd(here::here("data", "L2", "raw")) # set working directory to raw data folder
edat_L2 <- merge_webcam_files(vwp_paths_filtered_L2, screen_index=4) # eye
  tracking occurred on screen index 4
```

372 ***Subject and trial level data removal***

373 To ensure high-quality data, it is essential to filter out unreliable data based on both behavioral and
 374 eye-tracking criteria before merging datasets. In our dataset, participants will be excluded if they meet any
 375 of the following conditions: failure to successfully calibrate throughout the experiment (less than 100 trials),
 376 low accuracy ($< 80\%$), low sampling rates (< 5), and a high proportion of gaze data outside the screen
 377 coordinates ($> 30\%$). Successful calibration is crucial for capturing accurate eye-tracking measurements,
 378 so participants who could not maintain proper calibration may have inaccurate gaze data. Similarly, low
 379 accuracy may indicate poor engagement or task difficulty, which can reduce the reliability of the behavioral
 380 data and suggest that eye-tracking data may be less precise. In addition to this, we remove incorrect trials
 381 from remaining participants so we only look at correct trials.

382 First, we will create a cleaned up version of our behavioral, trial-level data L2_data by creating an
 383 object named eye_behav_L2 that selects useful columns from that file and renames stimuli to make them
 384 more intuitive. Because most of this will be user-specific, no function is called here. Below we describe
 385 the preprocessing done on the behavioral data file. The below code processes and transforms the L2_data
 386 dataset into a cleaned and structured format for further analysis. First, the code renames several columns for
 387 easier access using janitor::clean_names() (Firke, 2023) function. We then select only the columns we
 388 need and filter the dataset to include only rows where zone_type is “response_button_image”, representing
 389 the picture selected for that trial. Afterward, the function renames additional columns (tlpic to TL, trpic
 390 to TR, etc.). We also renamed participant_private_id to subject, spreadsheet_row to trial, and
 391 reaction_time to RT. This makes our columns consistent with the edat_L2 above for merging later on.
 392 Lastly, reaction_time (RT) is converted to a numeric format for further numerical analysis.

393 It is important to note here that what the behavioral spreadsheet denotes as trial is not in fact the trial
 394 number used in the eye-tracking files. Thus it is imperative you use spreadsheet_row as trial number to
 395 merge the two files successfully.

```
eye_behav_L2 <- L2_data %>%
  janitor::clean_names() %>%
  # Select specific columns to keep in the dataset
  dplyr::select(participant_private_id, correct, tlpic, trpic, blpic, brpic,
  ~ condition,
    eng_targetword, targetword, typetl, typetr, typebl, typebr,
  ~ zone_name,
    zone_type, reaction_time, spreadsheet_row, response) %>%
  # Filter the rows where 'Zone.Type' equals "response_button_image"
  dplyr::filter(zone_type == "response_button_image") %>%
```

```

# Rename columns for easier use and readability
dplyr::rename(
  TL = tlpic,          # Rename 'tlpic' to 'TL'
  TR = trpic,          # Rename 'trpic' to 'TR'
  BL = blpic,          # Rename 'blpic' to 'BL'
  BR = brpic,          # Rename 'brpic' to 'BR'
  targ_loc = zone_name, # Rename 'zone_name' to 'targ_loc'
  subject = participant_private_id, # Rename 'participant_private_id' to
  ~ 'subject'
  trial = spreadsheet_row, # Rename 'spreadsheet_row' to 'trial'
  acc = correct,         # Rename 'correct' to 'acc' (accuracy)
  RT = reaction_time    # Rename 'reaction_time' to 'RT'
) %>%
  # Convert the 'RT' (Reaction Time) column to numeric type
dplyr::mutate(RT = as.numeric(RT),
  subject = as.factor(subject),
  trial = as.factor(trial))

```

396 **Audio onset.** Because we are playing audio on each trial and running this experiment from the
 397 browser, audio onset is never going to be consistent across participants. In Gorilla there is an option to
 398 collect advanced audio features (you must make sure you select this when designing the study) such as when
 399 the audio play was requested, played, and ended. To do so you must click on advanced settings and select
 400 1 (see Figure 3). We will want to incorporate this timing information into our analysis pipeline. Gorilla
 401 records the onset of the audio which varies by participant. We are extracting that in the `audio_rt_L2` object
 402 by filtering `zone_type` to `content_web_audio` and a response equal to “AUDIO PLAY EVENT FIRED”.
 403 This will tell us when the audio was triggered in the experiment. We are creating a column called `(RT_audio)`
 404 which we will use later on to correct for audio delays. Please note that on some trials the audio may not play.
 405 This is a function of the browser a participant is using and the experimenter has no control over this (see <https://support.gorilla.sc/support/troubleshooting-and-technical/technical-checklist#autoplayingsoundandvideo>).

```

audio_rt_L2 <- L2_data %>%
  janitor::clean_names() %>%
  select(participant_private_id, zone_type, spreadsheet_row, reaction_time,
  ~ response) %>%

```

Figure 3*Advanced audio settings in Gorilla*

Web Audio ?

If 0 allow participant to start media manually. Choose 1 (start manually) or 0. Default: 1

Media can be played up to times. Default: 1

If (setting) advance when media is finished. Choose 1 (advance when finished) or 0. Default: 0

Advanced Settings + Show

If 1 , provide additional metrics on audio events Choose 1 for on or 0/unset for off. Default: 0/unset.

Audio format: mp3 . When playing audio files specified by embedded data, manually specify the format (usually wav or mp3) here. Default: mp3

Show Stop Button: (setting) . When playing audio, show a stop button allowing the audio file to be stopped. Choose 1 for on (show stop button), or 0/unset for off. Default: 0/unset

Show full audio controls: (setting) . Show a full set of controls for the audio file, allowing participants to play, pause, rewind etc. Choose 1 for on (show full controls), or 0/unset for off. Default: 0/unset

Localisation Settings ? Docs + Show

```

filter(zone_type=="content_web_audio", response=="AUDIO PLAY EVENT FIRED")%>%
  distinct() %>%
dplyr::rename("subject" = "participant_private_id",
  "trial" ="spreadsheet_row",
  "RT_audio" = "reaction_time",
  "Fired" = "response") %>%
select(-zone_type) %>%
mutate(RT_audio=as.numeric(RT_audio))

```

407 We then merge this information with eye_behav_L2.

```

# merge the audio Rt data to the trial level object
trial_data_rt_L2 <- merge(eye_behav_L2, audio_rt_L2, by=c("subject", "trial"))

```

408 **Trial removal.** As stated above, participants who did not successfully calibrate 3 times or less were
 409 rejected from the experiment. Deciding to remove trials is ultimately up to the researcher. In our case, we
 410 removed participants with less than 100 trials. Let's take a look at how many participants meet this criterion
 411 by probing the trial_data_rt_L2 object. In Table 2 we can see several participants failed some of the cal-
 412 ibration attempts and do not have an adequate number of trials. Again we make no strong recommendations
 413 here. If you decide to use a criterion such as this, we recommend pre-registering your choice.

```

# find out how many trials each participant had
edatntrials_L2 <- trial_data_rt_L2 %>%
  dplyr::group_by(subject)%>%
  dplyr::summarise(ntrials=length(unique(trial)))

```

414 Let's remove them participants with less than 100 trials from the analysis using the below code.

```

trial_data_rt_L2 <- trial_data_rt_L2 %>%
  filter(subject %in% edatntrials_bad_L2$subject)

```

415 **Low accuracy.** In our experiment, we want to make sure accuracy is high (> 80%). Again, we want
 416 participants that are fully attentive in the experiment. In the below code, we keep participants with accuracy
 417 equal to or above 80% and only include correct trials and assign it to trial_data_acc_clean_L2.

```

# Step 1: Calculate mean accuracy per subject and filter out subjects with mean
  ↳ accuracy < 0.8
subject_mean_acc_L2 <- trial_data_rt_L2 %>%

```

Table 2

Participants with less than 100 trials

subject	ntrials
12102265	2
12110638	55
12110829	59
12110878	59
12110897	60
12111234	57
12111244	58
12111363	58

12213826	99
12213965	59

```
group_by(subject) %>%
  dplyr::summarise(mean_acc = mean(acc, na.rm = TRUE)) %>%
  filter(mean_acc > 0.8)

# Step 2: Join the mean accuracy back to the main dataset and exclude trials with
# accuracy < 0.8
trial_data_acc_clean_L2 <- trial_data_rt_L2 %>%
  inner_join(subject_mean_acc_L2, by = "subject") %>%
  filter(acc==1) # only use accurate responses for fixation analysis
```

418 **RTs.** There is much debate on how to handle reaction time (RT) data (see Miller, 2023). Because
 419 of this, we leave it up to the reader and researcher to decide what to do with RTs. In this tutorial we leave
 420 RTs untouched.

421 **Sampling rate.** While most commercial eye-trackers sample at a constant rate, data captured by
 422 webcams are widely inconsistent. Below is some code to calculate the sampling rate of each participant.
 423 Ideally, you should not have a sampling rate less than 5 Hz. It has been recommended you drop those values
 424 (Bramlett & Wiener, 2024) The below function `analyze_sample_rate()` calculates the sampling rate for
 425 each subject and each trial in our eye-tracking dataset (`edat_L2`). The `analyze_sample_rate()` function
 426 provides overall statistics, including the option to report mean or median (Bramlett & Wiener, 2024) sampling
 427 rate and standard deviation of sampling rates in your experiment. The function also generates a histogram
 428 of sampling rates by subject. Looking at Figure 4, the sampling rate ranges from 5 to 35 Hz with a median
 429 sampling rate of 21.56. This corresponds to previous webcam eye-tracking work [e.g., Bramlett and Wiener
 430 (2024); Prystauka et al. (2024)]

```
samp_rate_L2 <- analyze_sampling_rate(edat_L2, summary_stat="median")
```

```
431 Overall median Sampling Rate (Hz): 21.56171771
432 Overall Standard Deviation of Sampling Rate (Hz): 7.399937723
433
434 Sampling Rate by Trial:

12110559	11,890.00	416.00	3.50	194.00	222.00	1.63	1.87
12110579	5,822.00	1,063.00	18.26	697.00	436.00	11.97	7.49
12110585	13,974.00	776.00	5.55	83.00	694.00	0.59	4.97

476 **Out-of-bounds (outside of screen).** It is important that we do not include points that fall outside
 477 the standardized coordinates (0,1). The `gaze_oob()` function calculates how many of the data points fall
 478 outside the standardized range. Here we need our eye-tracking data (`edat_L2`). Running the `gaze_oob()`
 479 function returns a table listing how many data points fall outside this range (total, X and Y), and also provides
 480 percentages (see Table 3). This information would be useful to include in the final

```
oob_data_L2 <- gaze_oob(edat_L2)
```

481 We can also add add by-participant and by-trial out of bounds data to our behavioral, trial-level, data
 482 (`filter_edat_L2`) and finally exclude participants and trials with more than 30% missing data. The value
 483 of 30 is just a suggestion and should not be used as a rule of thumb for all studies nor are we endorsing this
 484 value.

```
remove_missing <- oob_data_L2 %>%
  # Start with the `oob_data`  

  # dataset and assign the result to `remove_missing`  

  select(subject, total_missing_percentage) %>%
  # Select only the `subject`  

  # and `total_missing_percentage` columns from `oob_data`  

  left_join(filter_edat_L2, by = "subject") %>%
  # Perform a left join with  

  # `filter_edat` on the `subject` column, keeping all rows from `oob_data`  

  filter(total_missing_percentage < 30) %>%
  # Filter the data to keep  

  # only rows where `total_missing_percentage` is less than 30 %>%
  na.omit()
```

485 *Eye-tracking data*

486 **Convergence and confidence.** In the eye-tracking data we need to remove rows with poor convergence
 487 and confidence scores in our eye-tracking data. The convergence column refers to WebGazer.js
 488 confidence in finding a face (and accurately predicting eye movements). Confidence values vary from 0 to 1,
 489 and numbers less than 0.5 suggest that the model has probably converged. face_conf represents the support
 490 vector machine (SVM) classifier score for the face model fit. This score indicates how strongly the image
 491 under the model resembles a face. Values vary from 0 to 1, and here numbers greater than 0.5 are indicative
 492 of a good model fit. In our edat_L2 object we filter out convergence less than 0.5 and face confidence greater
 493 than 0.5 and save it to edat_1_L2

```
edat_1_L2 <- edat_L2 %>%
  dplyr::filter(convergence <= .5, face_conf >= .5) # remove poor convergnce and
  ↪ face confidence
```

494 **Combining eye and trial-level data.** Next, we will combine the eye-tracking data and behavioral
 495 data. In this case, we'll use right_join to add the behavioral data to the eye-tracking data. This en-
 496 sures that all rows from the eye-tracking data are preserved, even if there isn't a matching entry in the be-
 497 havioral data (missing values will be filled with NA). The resulting object is called dat_L2. We use the
 498 distinct() function afterward to remove any duplicate rows that may arise during the join

```
dat_L2 <- right_join(edat_1_L2,remove_missing, by = c("subject","trial"))

dat_L2 <- dat_L2 %>%
  distinct() # make sure to remove duplicate rows
```

499 **Areas of Interest**500 *Zone coordinates*

501 In the lab, we can control many aspects of the experiment that cannot be controlled online. Participants
 502 will be completing the experiment under a variety of conditions including, different computers, with
 503 very different screen dimensions. To control for this, Gorilla outputs standardized zone coordinates (labeled
 504 as x_pred_normalised and y_pred_normalised in the eye-tracking file) . As discussed in the Gorilla
 505 documentation, the Gorilla lays everything out in a 4:3 frame and makes that frame as big as possible. The
 506 normalized coordinates are then expressed relative to this frame; for example, the coordinate 0.5, 0.5 will
 507 always be the center of the screen, regardless of the size of the participant's screen. We used the normalized
 508 coordinates in our analysis (in general, you should always use normalized coordinates). However, there are
 509 a few different ways to specify the four coordinates of the screen, which are worth highlighting here.

Table 4

Quadrant coordinates in standardized space

loc	x_normalized	y_normalized	width_normalized	height_normalized	xmin	ymin	xmax	ymax
TL	0.00	0.50	0.50	0.50	0.00	0.50	0.50	1.00
TR	0.50	0.50	0.50	0.50	0.50	0.50	1.00	1.00
BL	0.00	0.00	0.50	0.50	0.00	0.00	0.50	0.50
BR	0.50	0.00	0.50	0.50	0.50	0.00	1.00	0.50

510 **Quadrant approach.** One way is to make the AOIs as big as possible, dividing the screen into four

511 quadrants. This approach has been used in several studies [e.g., (Bramlett & Wiener, 2024; Prystauka et al.,

512 2024). Table 4 lists coordinates for the quadrant approach and Figure 5 shows how each quadrant looks in

513 standardized space.

514 We plot all the fixations in each of the quadrants highlighted in different colors (Figure 5), removing

515 points outside the standardized screen space.

516 We plot all the fixations in each of the quadrants highlighted in different colors (Figure 5), removing

517 points outside the standardized screen space. As a note, we have decided to use an outer edge approach

518 here (eliminating eye fixations that extend beyond the screen coordinates). Bramlett and Wiener (2024) have

519 suggested an inner-edge approach and we may add this functionality once more testing is done. For now, we

520 believe that the outer edge approach leads to the least amount of bias in the eye-tracking pipeline.

521 **Matching conditions with screen locations.** The goal of the below code is to assign condition codes

522 (e.g., Target, Unrelated, Unrelated2, and Cohort) to each image in the dataset based on the screen location

523 where the image is displayed (e.g., TL, TR, BL, BR).

524 For each trial, the images are dynamically placed at different screen locations, and the code maps

525 each image to its corresponding condition based on these locations.

```
# Assuming your data is in a data frame called dat_L2
dat_L2 <- dat_L2 %>%
  mutate(
    Target = case_when(
      typetl == "target" ~ TL,
      typetr == "target" ~ TR,
      typebl == "target" ~ BL,
      typebr == "target" ~ BR,
      TRUE ~ NA_character_ # Default to NA if no match
    ),
  )
```

Figure 5

AOI coordinates in standardized space using the quadrant approach

Quadrants with Width Annotations

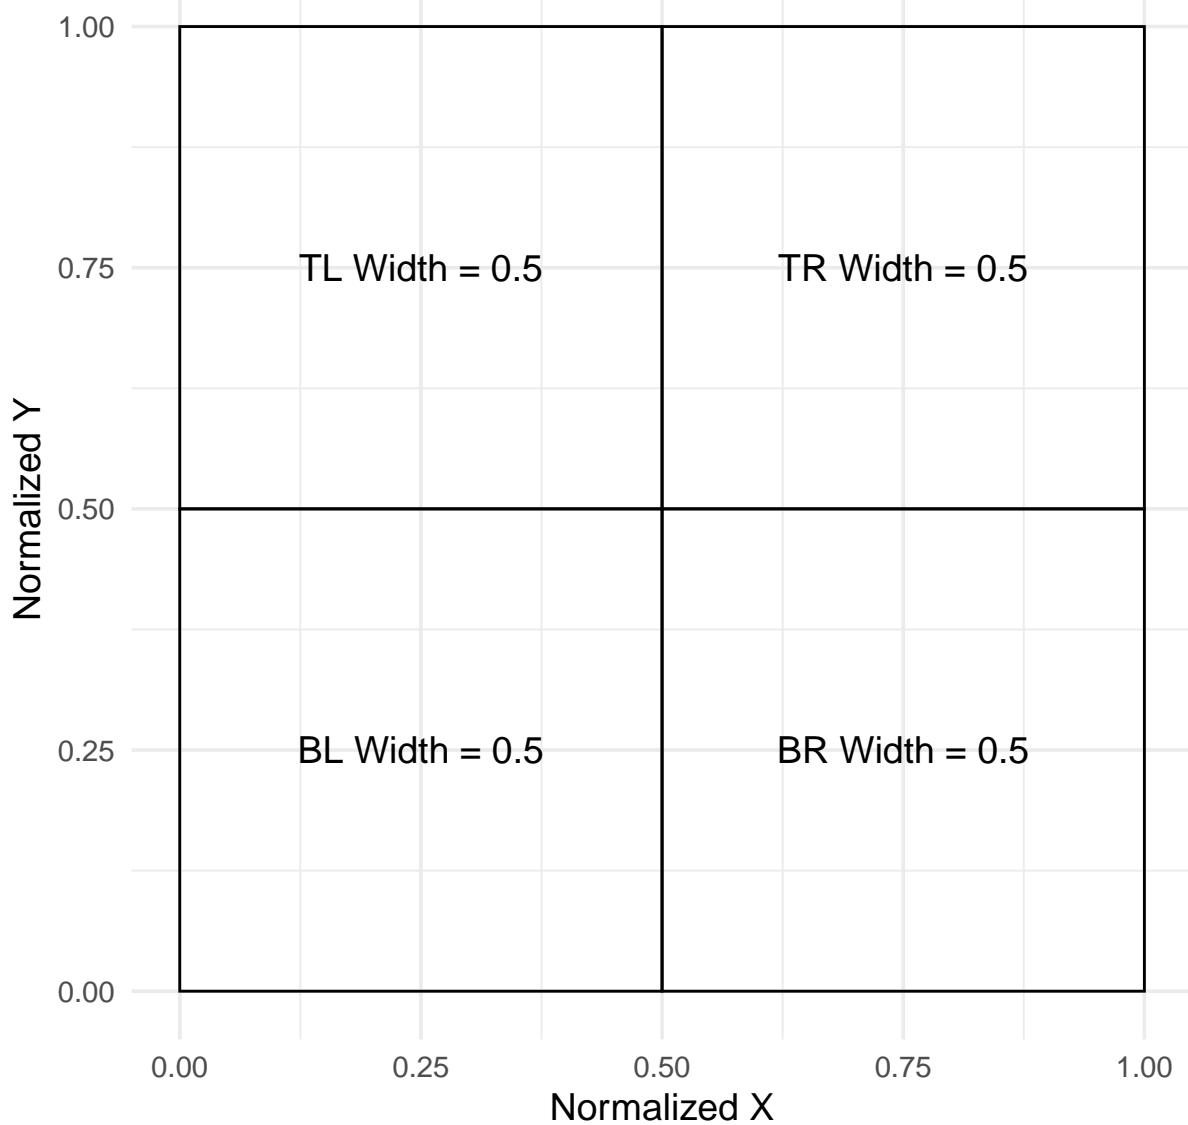

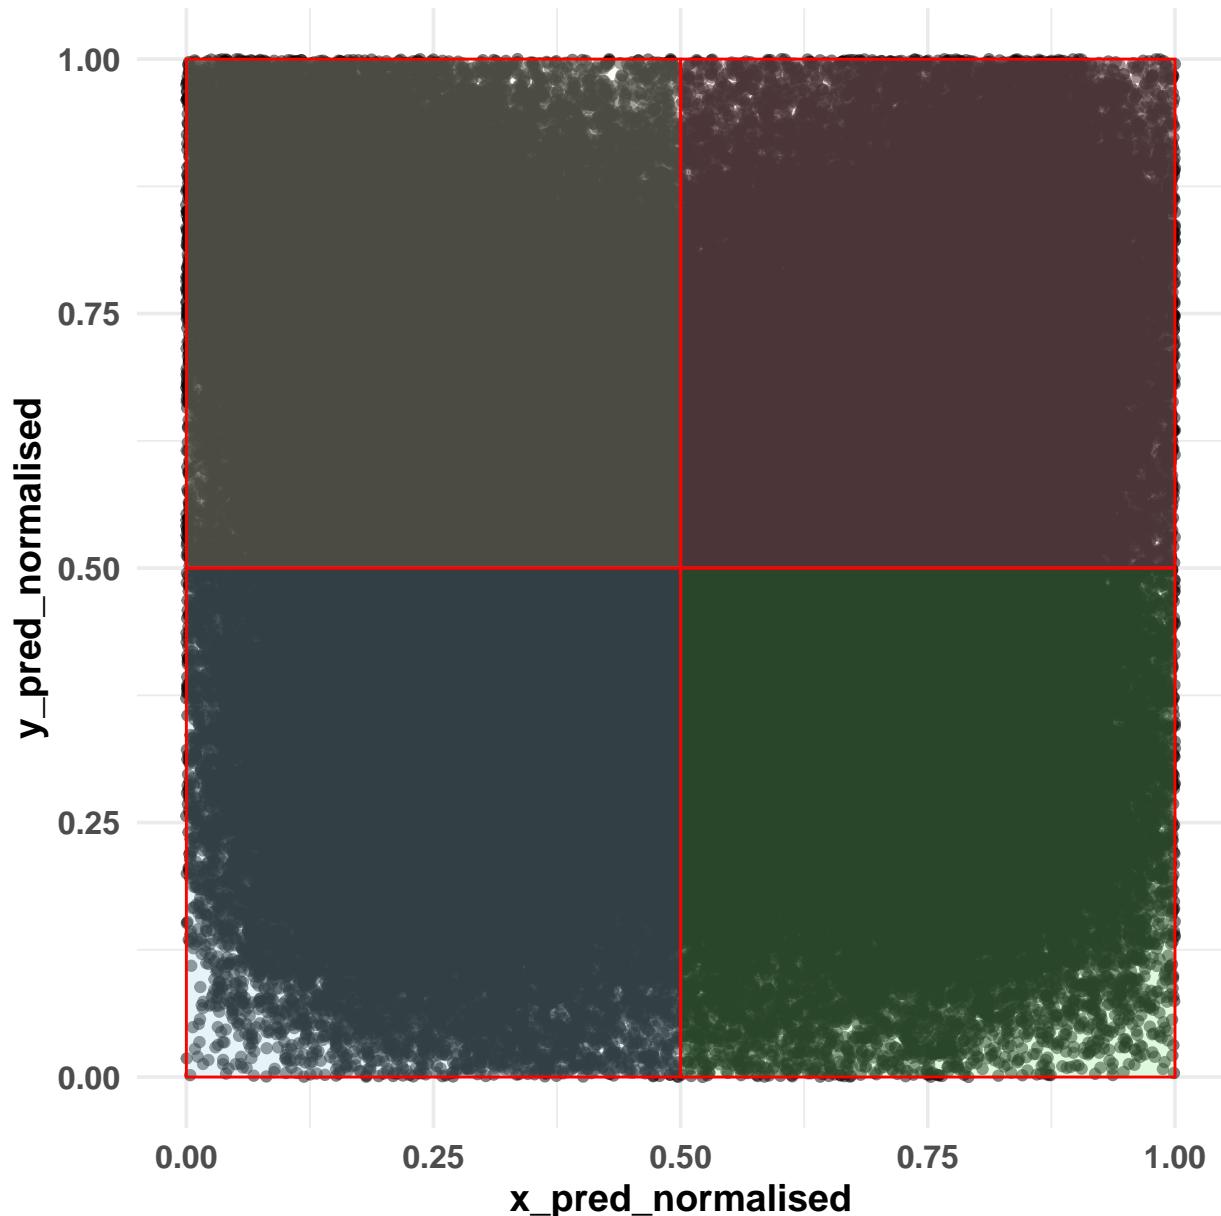

Figure 6

Looks to each quadrant of the screen

```

Unrelated = case_when(
  typetl == "unrelated1" ~ TL,
  typetr == "unrelated1" ~ TR,
  typebl == "unrelated1" ~ BL,
  typebr == "unrelated1" ~ BR,
  TRUE ~ NA_character_
),
Unrelated2 = case_when(
  typetl == "unrelated2" ~ TL,
  typetr == "unrelated2" ~ TR,
  typebl == "unrelated2" ~ BL,
  typebr == "unrelated2" ~ BR,
  TRUE ~ NA_character_
),
Cohort = case_when(
  typetl == "cohort" ~ TL,
  typetr == "cohort" ~ TR,
  typebl == "cohort" ~ BL,
  typebr == "cohort" ~ BR,
  TRUE ~ NA_character_
)
)
)

```

526 In addition to tracking the condition of each image during randomized trials, a custom function,
 527 `find_location()`, determines the specific screen location of each image by comparing it against the list
 528 of possible locations. This function ensures that the appropriate location is identified or returns NA if no
 529 match exists. Specifically, `find_location()` first checks if the image is NA (missing). If the image is NA,
 530 the function returns NA, meaning that there's no location to find for this image. If the image is not NA, the
 531 function creates a vector called `loc_names` that lists the names of the possible locations. It then attempts to
 532 match the given image with the locations. If a match is found, it returns the name of the location (e.g., TL,
 533 TR, BL, or BR) of the image.

```

# Apply the function to each of the targ, cohort, rhyme, and unrelated columns
dat_colnames_L2 <- dat_L2 %>%
  rowwise() %>%
  mutate(
    targ_loc = find_location(c(TL, TR, BL, BR), Target),
    cohort_loc = find_location(c(TL, TR, BL, BR), Cohort),
    unrelated_loc = find_location(c(TL, TR, BL, BR), Unrelated),
  )
)

```

```

unrealted2_loc= find_location(c(TL, TR, BL, BR), Unrelated2),
) %>%
ungroup()

```

534 Once we do this we can use the `assign_aoi()` function to loop through our object called
 535 `dat_colnames_L2` and assign locations (i.e., TR, TL, BL, BR) to where participants looked at on the screen.
 536 This requires the x and y coordinates and the location of our aois `aoi_loc`. Here we are using the quadrant
 537 approach. This function will label non-looks and off screen coordinates with NA. To make it easier to read
 538 we change the numerals assigned by the function to actual screen locations (e.g., TL, TR, BL, BR).

```

assign_L2 <- webgazeR::assign_aoi(dat_colnames_L2,X="x_pred_normalised",
← Y="y_pred_normalised",aoi_loc = aoi_loc)

AOI_L2 <- assign_L2 %>%

mutate(loc1 = case_when(
  AOI==1 ~ "TL",
  AOI==2 ~ "TR",
  AOI==3 ~ "BL",
  AOI==4 ~ "BR"
))

```

539 In `AOI_L2` we label looks to Targets, Unrelated, and Cohort items with 1 (looked) and 0 (no look)
 540 using the `case_when` function from the `tidyverse` (Wickham, 2017)

```

AOI_L2 <- AOI_L2 %>%
  mutate(
    target = case_when(loc1 == targ_loc ~ 1, TRUE ~ 0),
    unrelated = case_when(loc1 == unrelated_loc ~ 1, TRUE ~ 0),
    unrealted2 = case_when(loc1 == unrealted2_loc ~ 1, TRUE ~ 0),
    cohort = case_when(loc1 == cohort_loc ~ 1, TRUE ~ 0)
  )

```

541 The locations of looks need to be pivoted into long format—that is, converted from separate columns
 542 into a single column. This transformation makes the data easier to visualize and analyze. We use the
 543 pivot_longer() function from the tidyverse to combine the columns (Target, Unrelated, Unrelated2,
 544 and Cohort) into a single column called condition1. Additionally, we create another column called Looks,
 545 which contains the values from the original columns (e.g., 0 or 1 for whether the area was looked at).

```
dat_long_aoi_me_L2 <- AOI_L2 %>%
  select(subject, trial, condition, target, cohort, unrelated, unrelated2, time,
  ~ x_pred_normalised, y_pred_normalised, RT_audio) %>%
  pivot_longer(
    cols = c(target, unrelated, unrelated2, cohort),
    names_to = "condition1",
    values_to = "Looks"
  )
```

546 We further clean up the object by first cleaning up the condition codes. They have a numeral ap-
 547 pended to them and that should be removed. We then adjust the timing in the gaze_sub_L2_comp object by
 548 aligning time to the actual audio onset. To achieve this, we subtract RT_audio from time for each trial. In
 549 addition, we subtract 300 ms from this to account for the 100 ms of silence at the beginning of each audio
 550 clip and 200 ms to account for the oculomotor delay when planning an eye movement (Viviani, 1990). Ad-
 551 ditionally, we set our interest period between 0 ms (audio onset) and 2000 ms. This was chosen based on the
 552 time course figures in Sarrett et al. (2022) . It is important that you choose your interest area carefully and
 553 preferably you preregister it. The interest period you choose can bias your findings (Peelle & Van Engen,
 554 2021). We also filter out gaze coordinates that fall outside the standardized window, ensuring only valid data
 555 points are retained. The resulting object gaze_sub_long_L2 provides the corrected time column spanning
 556 from -200 ms to 2000 ms relative to stimulus onset with looks outside the screen removed.

```
# repalce the numbers appended to conditions that somehow got added
dat_long_aoi_me_comp <- dat_long_aoi_me_L2 %>%
  mutate(condition = str_replace(condition, "TCUU-SPENG\\d*", "TCUU-SPENG")) %>%
  mutate(condition = str_replace(condition, "TCUU-SPSP\\d*", "TCUU-SPSP"))%>%
  na.omit()
```

```
# dat_long_aoi_me_comp has condition corrected

gaze_sub_L2_long <-dat_long_aoi_me_comp%>%
  group_by(subject, trial, condition) %>%
  mutate(time = (time-RT_audio)-300) %>% # subtract audio rt onset and account
  ~ for occ motor planning and silence in audio
```

```
filter(time >= -200, time < 2000) %>%
  dplyr::filter(x_pred_normalised > 0,
                x_pred_normalised < 1,
                y_pred_normalised > 0,
                y_pred_normalised < 1)
```

557 **Samples to bins**

558 ***Downsampling***

559 Downsampling into smaller time bins is a common practice in gaze data analysis, as it helps create a
 560 more manageable dataset and reduces noise. When using research grade eye-trackers, downsampling is often
 561 not needed. However, with consumer-based webcam eye-tracking it is recommended you downsample your
 562 data so participants have consistent bin sizes (e.g., (Slim & Hartsuiker, 2023)). In webgazeR we included the
 563 `downsample_gaze()` function to assist with this process. We apply this function to the `gaze_sub_L2_long`
 564 object, and set the `bin.length` argument to 100, which groups the data into 100-millisecond intervals. This
 565 adjustment means that each bin now represents a 100 ms passage of time. We specify `time` as the variable
 566 to base these bins on, allowing us to focus on broader patterns over time rather than individual millisecond
 567 fluctuations. There is no agreed upon downsampling value, but with webcam data larger bins are preferred
 568 (Slim & Hartsuiker, 2023).

569 In addition, the `downsample_gaze()` allows you to aggregate across other variables, such as
 570 `condition`, `condition1`, and use the newly created `time_bins` variable, which represents the time
 571 intervals over which we aggregate data. The resulting downsampled dataset, output as Table 5, provides a
 572 simplified and more concise view of gaze patterns, making it easier to analyze and interpret broader trends.

```
gaze_sub_L2 <- webgazeR::downsample_gaze(gaze_sub_L2_long, bin.length=100,
                                         ← timevar="time", aggvars=c("condition", "condition1", "time_bin"))
```

573 To simplify the analysis, we combine the two unrelated conditions and average them (this is for the
 574 proportional plots).

```
# Average Fix for unrelated and unrelated2, then combine with the rest
gaze_sub_L2_avg <- gaze_sub_L2 %>%
  group_by(condition, time_bin) %>%
  summarise(
    Fix = mean(Fix[condition1 %in% c("unrelated", "unrelated2")], na.rm =
      ← TRUE),
    condition1 = "unrelated", # Assign the combined label
```

Table 5

Aggregated proportion looks for each condition in each 100 ms time bin

condition	condition1	time_bin	Fix
TCUU-ENGSP	cohort	-200.00	0.26
TCUU-ENGSP	cohort	-100.00	0.26
TCUU-ENGSP	cohort	0.00	0.25
TCUU-ENGSP	cohort	100.00	0.26
TCUU-ENGSP	cohort	200.00	0.23
TCUU-ENGSP	cohort	300.00	0.22

```

  .groups = "drop"
) %>%
# Combine with rows that do not include unrelated or unrelated2
bind_rows(gaze_sub_L2 %>% filter(!condition1 %in% c("unrelated",
  ~ "unrelated2")))

```

575 The above will not include the subject variable. If you want to keep participant-level data we need
 576 to add `subject` to the `aggvars` argument.

```

# add subject-level data
gaze_sub_L2_id <- webgazeR::downsample_gaze(gaze_sub_L2_long, bin.length=100,
  ~ timevar="time", aggvars=c("subject", "condition", "condition1", "time_bin"))

```

577 Aggregation is an optional step. If you do not plan to analyze proportion data, and instead what time
 578 binned data with binary outcomes preserved please set the `aggvars` argument to “none.” This will return a
 579 time binned column, but will not aggregate over other variables.

```

# get back trial level data with no aggregation
gaze_sub_id <- downsample_gaze(gaze_sub_L2_long, bin.length=100, timevar="time",
  ~ aggvars="none")

```

580 We need to make sure we only have one unrelated value.

```

gaze_sub_id <- gaze_sub_id %>%
  mutate(condition1 = ifelse(condition1=="unrelated2", "unrelated", condition1))

```

581 **Visualizing time course data**

582 To simplify plotting your time-course data, we have created the `plot_IA_proportions()` function.
 583 This function takes several arguments. The `ia_column` argument specifies the column containing
 584 your AOI labels. The `time_column` argument requires the name of your time bin column, and the
 585 `proportion_column` argument specifies the column containing fixation or look proportions. Additional
 586 arguments allow you to specify custom names for each IA in the `ia_mapping` argument, enabling you to
 587 label them as desired. In order to use this function, you must use the `downsample_gaze()` function.

588 Below, we have plotted the time-course data for each condition in Figure 7. By default, the graphs
 589 utilize a color-blind-friendly palette from the `ggokabeito` package (Barrett, 2021). However, you can set
 590 the argument `use_color = FALSE` to generate a non-colored version of the figure, where different line types
 591 and shapes differentiate conditions. Additionally, since these are `ggplot` objects, you can further customize
 592 them as needed to suit your analysis or presentation preferences.

Figure 7

Comparison of L2 competition effect in the No Competitor (a), Spanish–English (b), the Spanish–Spanish (c) conditions

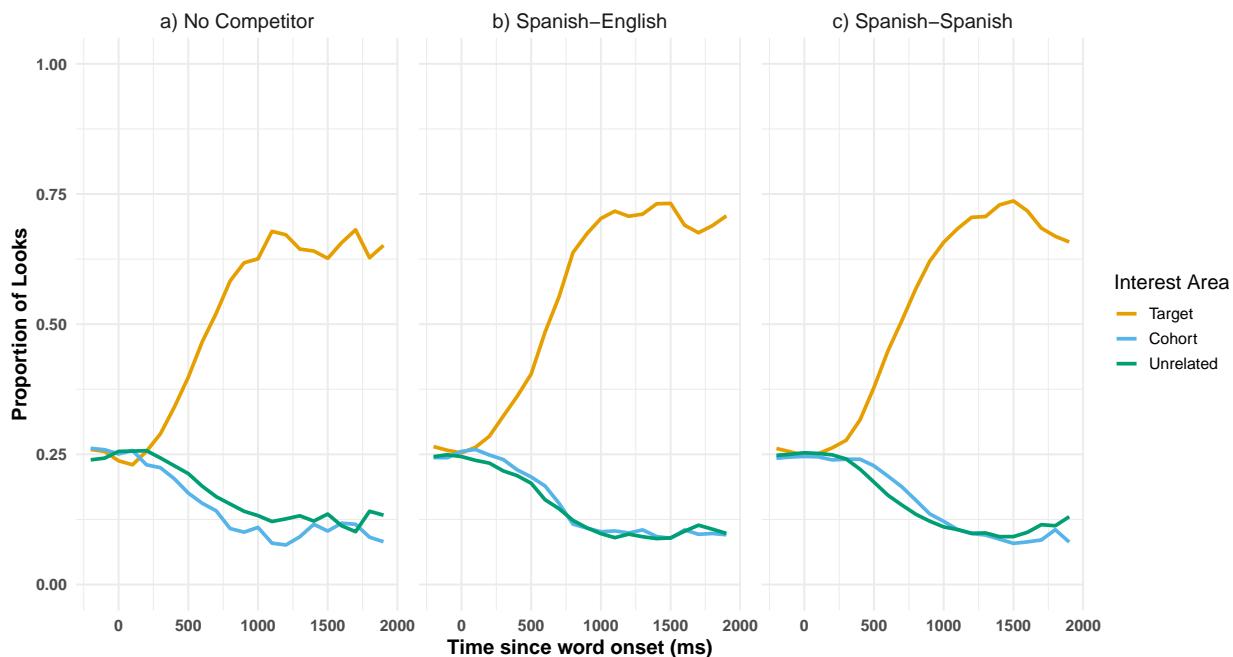

Table 6

Gorilla provided standarized gaze coordinates

loc	x_normalized	y_normalized	width_normalized	height_normalized	xmin	ymin	xmax	ymax
BL	0.03	0.04	0.26	0.25	0.03	0.04	0.29	0.29
TL	0.02	0.74	0.26	0.25	0.02	0.74	0.28	0.99
TR	0.73	0.75	0.24	0.24	0.73	0.75	0.97	0.99
BR	0.73	0.06	0.23	0.25	0.73	0.06	0.96	0.31

593 **Gorilla provided coordinates**

594 Thus far, we have used the coordinates representing the four quadrants of the screen. However,
 595 Gorilla provides their own quadrants representing image location on the screen. To the authors' knowledge,
 596 these quadrants have not been looked at in any studies reporting eye-tracking results. Let's examine how
 597 reasonable our results are with the Gorilla provided coordinates.

598 We will use the function `extract_aois()` to get the standardized coordinates for each quadrant on
 599 screen. You can use the `zone_names` argument to get the zones you want to use. In our example, we want the
 600 TL, BR, BL TR coordinates. We input the object from above `vwp_paths_filtered_L2` that contains all our
 601 eye-tracking files and extract the coordinates we want. These are labeled in Table 6. In Figure 8 we can see
 602 that the AOIs are a bit smaller than then when using the quadrant approach. We can take these coordinates
 603 and use them in our analysis.

604 We are not going to highlight the steps here as they are the same as above. we are just replacing the
 605 coordinates.

```
# apply the extract_aois fucntion
aois_L2 <- extract_aois(vwp_paths_filtered_L2, zone_names = c("TL", "BR", "TR",
  ↵ "BL"))
```

```
assign_L2_gor <- webgazeR::assign_aoi(dat_colnames_L2, X="x_pred_normalised",
  ↵ Y="y_pred_normalised", aoi_loc = aois_L2)
```

606 **Visualizing time course data with Gorilla coordinates**

607 The Gorilla provided coordinates show a similar pattern to the quadrant approach. However, the
 608 time course looks a bit nosier given the smaller AOIs.

Figure 8

Gorilla provided standardized coordinates for the four quadrants on the screen

Comparison of competition effects with Gorilla standardized coordinates

609 Modeling data

When analyzing VWP data there are many analytic approaches to choose from (e.g., growth curve analysis (GCA), cluster permutation tests (CPT), generalized additive mixed models (GAMMS), logistic multilevel models, divergent point analysis, etc.), and a lot has already been written describing these methods and applying them to visual world fixation data from the lab (see Ito & Knoeferle, 2023; McMurray & Kutlu, n.d.; Stone et al., 2021) and online (Bramlett & Wiener, 2024). This tutorial's goal, however, is to not evaluate different analytic approaches and tell readers what they should use. All methods have their strengths and weaknesses (see Ito & Knoeferle, 2023). Nevertheless, statistical modeling should be guided by the questions researchers have and thus serious thought needs to be given to the proper analysis. In the VWP, there are two general questions one might be interested in: (1) Are there any overall difference in fixations between conditions and (2) Are there any time course differences in fixations between conditions

620 (and/or groups).

621 With our data, one question we might want to answer is if there are any fixation differences between
622 the cohort and unrelated conditions across the time course. One statistical approach we chose to highlight
623 to answer this question is a cluster permutation analysis (CPA). The CPA is suitable for testing differences
624 between two conditions or groups over an interest period while controlling for multiple comparisons and
625 autocorrelation.

626 **CPA**

627 CPA is a technique that has become increasingly popular, particularly in the field of cognitive neu-
628 ropsychology, for analyzing MEG and EEG data (Maris & Oostenveld, 2007). While its adoption in VWP
629 studies has been relatively slow, it is now beginning to appear more frequently (see Huang & Snedeker, 2020;
630 Ito & Knoeferle, 2023). Notably, its use is growing in online eye-tracking studies (see Slim et al., 2024; Slim
631 & Hartsuiker, 2023; Vos et al., 2022).

632 Before I show you how to apply this method to the current dataset, I want to briefly explain what
633 CPA is. The CPA is a data-driven approach that increases statistical power while controlling for Type I errors
634 across multiple comparisons—exactly what we need when analyzing fixations across the time course.

635 The clustering procedure involves three main steps:

636 The clustering procedure involves three main steps:

637 1. Cluster Formation: With our data, a multilevel logistic model is conducted for every data point (con-
638 dition by time). Please note that any statistical test can be run here. Adjacent data points that surpass
639 the mass univariate significance threshold (e.g., $p < .05$) are combined into clusters. The cluster-
640 level statistic, typically the sum of the t-values (or F-values) within the cluster, is computed labeled
641 as SumStatistic is output below). By clustering adjacent significant data points, this step accounts for
642 autocorrelation by considering temporal dependencies rather than treating each data point as indepen-
643 dent.

644 2. Null Distribution Creation: Next, the same analysis is run as in step 1. However, the analysis is based
645 on randomly permuting or shuffling the conditions within subjects. This principle of exchangeability is
646 important here, as it suggests that the condition labels can be exchanged without altering the underlying
647 data structure. This randomization is repeated n times (e.g., 1000 shuffles), and for each permutation,
648 the cluster-level statistic is computed. This step addresses the issue of multiple comparisons by con-
649 structing a distribution of cluster-level statistics under the null hypothesis, providing a baseline against
650 which observed cluster statistics can be compared. By doing so, the method controls the family-wise
651 error rate and ensures that significant findings are not simply due to chance.

652 3. Significance Testing: The cluster-level statistics from the observed (real) comparison is compared to
653 the null distribution we created above. Clusters with statistics falling in the highest or lowest 2.5% of
654 the null distribution are considered significant (e.g., $*p* < 0.05$).

655 To perform CPA, we will load in the `permutes` (Voeten, 2023), `permuco` (Frossard & Renaud,
 656 `foreach` (& Weston, 2022), and `Parallel` (Corporation & Weston, 2022) packages in R. Loading
 657 these packages allow us to use the `cluster.glmer()` function to run a cluster permutation (10,000 rimes)
 658 across multiple system cores to speed up the process. We run a CPA on the `gaze_sub_id` object where each
 659 row in `Looks` denotes whether the AOI was fixated, with values of zero (not fixated) or one (fixated).

660 Below you find sample code to perform multilevel CPA in R (please see the Github repository for
 661 elaborated code needed to perform CPA).

```
library(permutes) # cpa
library(permuco) # cpa
library(foreach) # for par processing
library(doParallel)

# Step 1: Set up parallel backend
num_cores <- detectCores() - 1 # Use all available cores minus one for system
#<-- stability
cl <- makeCluster(num_cores)
registerDoParallel(cl)

# Step 2: Define the total number of permutations
total_perms <- 1000

# Step 3: Split the permutations across available cores
perms_per_core <- total_perms / num_cores

# Step 4: Use foreach to run the function in parallel
cpa.lme <- foreach(i = 1:num_cores, .combine = 'rbind', .packages = 'permutes')
#<-- %dopar% {
  permutes::clusterperm.glmer(Looks~ condition1_code + (1|subject) + (1|trial),

```

662 In the analysis for the Spanish-Spanish condition, one significant cluster was observed between
 663 500 and 1,100 ms, as indicated in the summary statistics from Table 7. The positive SumStatistic value
 664 associated with this cluster suggests that competition was greater during this time window. This result im-
 665 plies that cohorts in the Spanish-Spanish condition exhibited stronger effects or competition compared to
 666 unrelated items. In Figure 10 significant clusters are highlighted for both the Spanish-Spanish and Spanish-

Table 7

Clustermass statistics for the Spanish-Spanish condition

cluster	cluster_mass	p.cluster_mass	bin_start	bin_end	t	sign	time_start	time_end	
1	210.03		0	7	13	5.14	1	500	1,100

667 English conditions. Both conditions show one significant cluster. Overall, the analysis suggests that both
 668 the Spanish-Spanish and Spanish-English conditions demonstrate significant competitor effects.

669 Discussion

670 Webcam eye-tracking is a relatively nascent technology, and as such, there is limited guidance avail-
 671 able for researchers. To ameliorate this, we created a tutorial to assist new users of visual world webcam
 672 eye-tracking, using some of the best practices available (e.g., Bramlett & Wiener, 2024). To further facil-
 673 itate this process, we created the `webgazeR` package, which contains several helper functions designed to
 674 streamline data preprocessing, analysis, and visualization.

675 In this tutorial, we covered the basic steps of running a visual world webcam-based eye-tracking
 676 experiment. We highlighted these steps by using data from a cross-linguistic VWP looking at competitive
 677 processes in L2 speakers of Spanish. Specifically, we attempted to replicate the experiment by Sarrett et al.
 678 (2022) where they observed within- and between L2/L1 competition using carefully crafted materials.

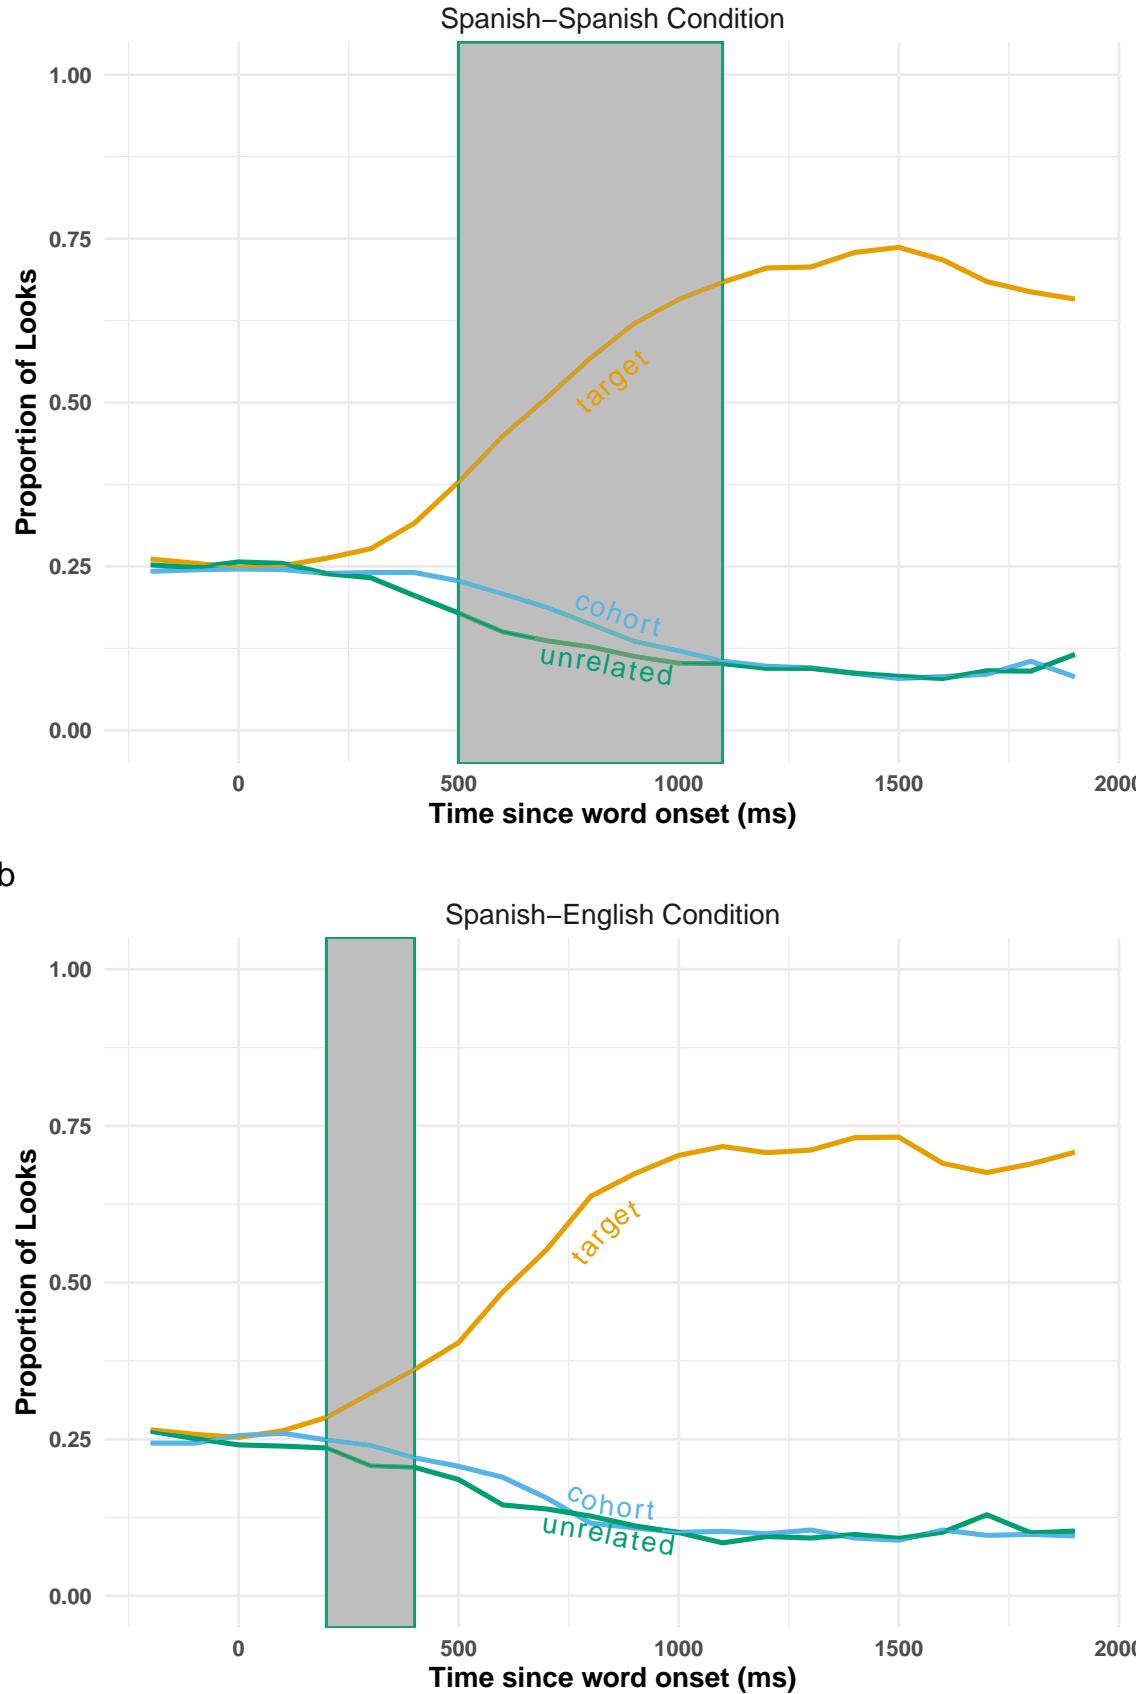

679 While the main purpose of this tutorial was to highlight the steps needed to analyze webcam eye-
 680 tracking data, replicating Sarrett et al. (2022) allowed us to not only assess whether within and between L2/L1
 681 competition can be found in a spoken word recognition VWP experiment online (one of the first studies to
 682 do so), but also provide insight in how to run VWP studies online and the issues associated with it.

683 Our conceptual replication findings are highly encouraging, demonstrating competition effects both
 684 within (the Spanish-Spanish condition) and across languages (the Spanish-English condition), closely paral-
 685 leling the results reported by Sarrett et al. However, several important methodological and sample differences
 686 war

687 A key methodological difference between our study and Sarrett et al. lies in the approach used to
 688 analyze the time course of competition. While they employed a non-linear curve-fitting method (see McMurr-
 689 ray et al., 2010), we used CPA. This methodological distinction limits our ability to address similar temporal
 690 questions. Nonetheless, the overall temporal patterns are strikingly similar. For instance, our CPA revealed
 691 a significant cluster starting at 500 ms, whereas Sarrett et al. (2022) identified competition effects emerging
 692 at approximately 400 ms. This indicates a delay of about 100 ms in competition onset between lab-based
 693 and online eye-tracking data. This delay, while notable, reflects a significant improvement over previous
 694 webcam-based studies (e.g., Semmelmann & Weigelt, 2018; Slim et al., 2024). It is important to emphasize,
 695 however, that CPA clusters cannot reliably be used to make temporal inferences about the onset/offset of

Figure 10

Average looks in the cross-linguistic VWP task over time for the Spanish-Spanish condition (a) and the Spanish-English condition (b). The shaded rectangles indicate when cohort looks were greater than chance based on the CPA.

696 effects (Fields & Kuperberg, 2019; Ito & Knoeferle, 2023).

697 Our study also employed a truncated stimulus set, with only 250 trials compared to the 450 trials in
698 the original study.¹ Despite this reduction, the number of trials in our study remains larger than most existing
699 webcam-based studies. Even with the smaller set, we observed a similar pattern of competition effects in
700 both the Spanish-Spanish and Spanish-English conditions, demonstrating the robustness of our findings.

701 Another notable difference is the recruitment strategy and participant screening. Sarrett et al. re-
702 cruted participants from a Spanish college course and used the LexTALE-Spanish assessment (Izura et al.,
703 2014) to evaluate Spanish proficiency. In contrast, our data were collected via Prolific with limited filters,
704 which only allowed us to screen for native language and experience with another language. This constraint
705 limited our ability to refine participant selection further and likely contributed to differences in participant
706 profiles. While Sarrett et al. focused on adult L2 learners with known language proficiency levels, our sample
707 included a broader range of L2 speakers with limited checks on their language abilities (see Table 1 for range
708 of Spanish speakers in our study). This may help explain why we did not observe a cohort competition effect
709 that persisted across the time course as observed by Sarrett et al.

710 Overall, while the methodological and sample differences between the two studies are notable, the
711 similarities in the competition effects observed within and across languages reinforce the robustness of these
712 findings across different research settings. While we do not wish to downplay our findings, a more systematic
713 study is needed to ensure generalizability.

714 Limitations

715 While the above suggests that webcam eye-tracking is a promising avenue for language research,
716 there are some issues that we ran into that need to be addressed. One issue is data loss due to poor calibration.
717 In our study, we had to throw out ~40% of our data due to poor calibration. Other studies have shown numbers
718 much higher (e.g., 73%) (Slim & Hartsuiker, 2023) and lower (e.g., 20%) (Prystauka et al., 2024). Given this,
719 it is still an open question as to what contributes to better vs. poor data quality in webcam eye-tracking. To
720 this end, we included an assessment after the VWP that included questions on the participants' experimental
721 set-ups and overall experiences with the eye-tracking experiment. All questions are included Table 8.

722 Poor vs. good calibrators

723 In our experimental design, participants were branched based on whether they successfully com-
724 pleted the experiment or failed calibration at any point. Table 9 highlights the comparisons between good
725 and poor calibrators. For the sake of brevity, we do not include responses to all questions. You can look
726 at all the responses at our repo. However, two key differences emerge that may provide insight into factors
727 influencing successful calibration.

728 One notable difference is the type of webcam used. Participants who failed calibration predomi-

¹The curve fitting approach employed by Sarrett et al. (2022) necessitates more trials. If we were to apply that approach the number of trials needed might not be sufficient.

729 nantly reported using built-in webcams, whereas those who successfully calibrated reported using a variety
730 of external webcams. This suggests that built-in webcams may not provide adequate resolution for effec-
731 tive calibration in the experiment. In fact, Slim and Hartsuiker (2023) examined the relationship between
732 calibration scores and frame rate, finding that higher frame rates were associated with improved calibration
733 performance. Participants using higher-quality webcams may have an easier time calibrating thereby leading
734 to more reliable gaze data.

735 Another difference lies in the participants' environmental setup. Individuals who failed calibration
736 were more likely to be in environments with natural light. Since natural light is known to interfere with
737 eye-tracking, it may have contributed to their inability to calibrate successfully.

738 We did not notice any other differences between those that successfully calibrated vs. those who
739 did not. For researchers wanting to use webcam eye-tracking, they should try to make sure participants
740 are in rooms without natural light, and use good web cameras. While we tried to emphasize this in our
741 instructional videos, more explicit instruction may be needed. An avenue for research would be to compare
742 lab based webcam eye-tracking to online based webcam eye tracking to see if control of the environment can
743 produce better results.

744 It is important to note here that Gorilla uses WebGazer.js (Papoutsaki et al., 2016) to perform it's
745 eye tracking. It is unclear if poor calibration results from the noise introduced by participants' environ-
746 ments/equipment or if it is a function of the method itself, or both. We have listed some equipment and
747 environmental factors that may contribute to the poor performance; however it could be the algorithm itself
748 that is poor. There are other experimental platforms out there that use different eye-tracking ML algorithms
749 to perform webcam eye-tracking. Labvanced (Kaduk et al., 2024), for example, offers additional eye-tracking
750 functionality including a virtual chinrest to ensure head movement is restricted to an acceptable range and
751 warns users if they deviate from this range. Together this might make for a better eye-tracking experience
752 with less data thrown out. This should be investigated further.

753 ***Generalizability to other platforms***

754 We demonstrated how to analyze webcam eye-tracking data from a Gorilla experiment using We-
755 bGazer.js. While we were unable to validate this pipeline on other experimental platforms using WebGazer.js,
756 such as PCIbex (Zehr & Schwarz, 2018) or jsPsych (Leeuw, 2015), we believe that this basic pipeline will
757 generalize to those platforms, as WebGazer.js underlies them all and provides consistent output. We encour-
758 age researchers to test this pipeline in their own studies and report any issues on our GitHub repository. We
759 are committed to continuing improvements to `webgazeR`, ensuring that users can effectively analyze webcam
760 eye-tracking data with our package.

761 ***Power***

762 While we successfully demonstrated competition effects similar to Garrett's study, we did not conduct
763 an a priori power analysis nor was it our intention. With webcam eye-tracking, it has been recommended

Table 8*Eye-tracking questionnaire items*

Question
1. Do you have a history of vision problems (e.g., corrected vision, eye disease, or drooping eyelids)?
2. Are you on any medications currently that can impair your judgement?
If yes, please list below:
4. Does your room currently have natural light?
5. Are you using the built in camera?
If no, what brand of camera are you using?
6. Please estimate how far you think you were sitting from the camera during the experiment (an arm's length etc.)
7. Approximately how many times did you look at your phone during the experiment?
8. Approximately how many times did you get up during the experiment?
9. Was the environment you took the experiment in distraction free?
10. When you had to calibrate, were the instructions clear?
11. What additional information would you add to help make things easier to understand?
12. Are you wearing a mask?

⁷⁶⁴ running twice the number of participants from the original sample, or powering the study to detect an effect
⁷⁶⁵ size half as large as the original (Slim & Hartsuiker, 2023; also see Simonsohn, 2015). We did attempt
⁷⁶⁶ to increase our sample size 2x, but were unable to recruit enough participants through Prolific. However,
⁷⁶⁷ our sample size is similar to the lab based studies. Regardless, researchers should be aware of this and plan
⁷⁶⁸ accordingly.

⁷⁶⁹ We strongly urge researchers to perform power analyses and justify their sample sizes (Lakens, 2022).
⁷⁷⁰ While tools like G*Power (Faul et al., 2007) are available for this purpose, we recommend power simulations
⁷⁷¹ using Monte Carlo or resampling methods on pilot or sample data (see Prystauka et al., 2024; Slim & Hart-
⁷⁷² suiker, 2023). Several excellent R packages, such as `mixedpower` (Kumle et al., 2021) and `SIMR` (Green &
⁷⁷³ MacLeod, 2016) make such simulations straightforward and accessible.

⁷⁷⁴ **Recommendations**

⁷⁷⁵ Based on our findings and limitations, we propose the following recommendations for researchers
⁷⁷⁶ conducting visual world webcam eye-tracking experiments.

⁷⁷⁷ **1. Prioritize external webcams**

Table 9

Responses to eye-tracking questions for participants who successfully calibrated vs. participants who had trouble calibratrin

Question	Response
1. Do you have a history of vision problems (e.g., corrected vision, eye disease, or drooping eyelids)?	No
1. Do you have a history of vision problems (e.g., corrected vision, eye disease, or drooping eyelids)?	Yes
2. Are you on any medications currently that can impair your judgement?	No
2. Are you on any medications currently that can impair your judgement?	Yes
4. Does your room currently have natural light?	No
4. Does your room currently have natural light?	Yes
5. Are you using the built in camera?	No
5. Are you using the built in camera?	Yes
9. Was the environment you took the experiment in distraction free?	No
9. Was the environment you took the experiment in distraction free?	Yes

778 Our questionnaire suggested that participants using external webcams had significantly better calibration
 779 success compared to those relying on built-in webcams. External webcams generally provide
 780 higher resolution and frame rates, which are critical for accurate eye-tracking. Researchers should
 781 encourage participants to use external webcams whenever possible.

782 **2. Optimize environmental conditions**

783 Natural light was a common factor in environments where calibration failed. Researchers should advise
 784 participants to conduct experiments in rooms with controlled lighting—ideally, artificial lighting with
 785 minimal glare or shadows—to reduce interference with eye-tracking accuracy.

786 **3. Conduct a priori power analysis**

787 To ensure adequate statistical power, researchers should conduct a priori power analyses either via GUI
 788 like GPower or perform Monte Carlo simulations/resampling on pilot data. This step is particularly
 789 important for online studies, where sample variability can be higher than in controlled lab environ-
 790 ments. To this point, you will have to over-enroll your study due to high attrition rate to reach your
 791 target goal, so please plan accordingly.

792 **4. Collect detailed post-experiment feedback**

793 Including post-experiment questionnaires about participants' setups (e.g., webcam type, browser, light-
 794 ing conditions) can provide valuable insights into calibration success factors. These data can help refine
 795 participant instructions and inclusion criteria for future studies.

796 By adhering to these recommendations, researchers can enhance the reliability and generalizability
797 of their webcam eye-tracking studies, ensuring the potential of this technology is fully realized.

798 **Conclusions**

799 This work highlighted the steps required to process webcam eye-tracking data collected via Gorilla,
800 showcasing the potential of webcam-based eye-tracking for robust psycholinguistic experimentation. With a
801 standardized pipeline for processing eye-tracking data we hope we have given researchers a clear path forward
802 when collecting and analyzing visual word webcam eye-tracking data.

803 Moreover, our findings demonstrate the feasibility of conducting high-quality online experiments,
804 paving the way for future research to address more nuanced questions about L2 processing and language
805 comprehension more broadly. Additionally, further refinement of webcam eye-tracking methodologies could
806 enhance data precision and extend their applicability to more complex experimental designs. This is an
807 exciting time for eye-tracking research, with its boundaries continuously expanding. We eagerly anticipate
808 the advancements and possibilities that the future of webcam eye-tracking will bring.
